Audio Video Engineering Concepts Explained

Signal Flow in Audio Production

Signal flow is the path a sound takes from source to output. In a typical studio:

- Microphone captures the sound.
- Pre amp boosts the signal.
- Mixing console balances levels.
- Outboard gear (compressor, EQ) processes the signal.
- Digital Audio Workstation (DAW) records and edits.
- Mastering chain finalizes the track.

Compression and Dynamics

Compression reduces the dynamic range of an audio signal, making quiet parts louder and loud parts quieter. The key parameters are:

- Threshold: The level at which compression kicks in.
- Ratio: The amount of gain reduction per dB above the threshold.
- Attack: How quickly the compressor reacts.
- Release: How quickly the compressor stops affecting the signal.
- Make up Gain: Compensates for the loss in overall level.

Video Encoding Basics

Encoding compresses raw video data into a manageable file size while preserving quality. The process involves:

- Intra frame compression: Each frame is compressed independently.
- Inter frame compression: Only differences between frames are stored.
- Bitrate: Determines how much data is used per second of video.
- Codec: Algorithms like H.264 or AV1 define how compression is performed.

Synchronization Techniques

Keeping audio and video perfectly aligned is crucial. Common methods include:

- Timecode: A standardized clock that tags each frame and sample.
- SMPTE: A widely used timecode format for film and broadcast.
- MIDI Timecode: Used in live performances to sync instruments.
- Click Tracks: A metronome track used during recording to lock tempo.
